ABSTRACT

This thesis generates closed-form equations for significant and frequently used NATOPS performance charts for the H-46D and H-46A (with T58-GE-10 engines) helicopters. These equations are developed into interactive software for the Hewlett-Packard HP-41CV hand-held programmable calculator. With this software installed in the calculator the user is able to calculate numerous NATOPS performance parameters (expeditiously, with reduced risk of error) both prior to and in flight.

I. INTRODUCTION

A. COORDINATION OF EFFORT

A similar software development for the H-3D and H-3H helicopters was conducted at the same time as this development by Curtis [Ref. 1]. Because of the nature and complexity of the problem, the initial stages of these investigations were a joint effort. As a result, the Approach to the Problem (Chapter II) and the basic method of the Solution (Chapter III) of this work and of Reference 1 are very similar.

B. BACKGROUND

Performance planning is an essential task to ensure the safe conduct of any aircraft and crew during their flight. Naval aircrew use the Naval Air Training and Operating Procedure Standardization (NATOPS) manual to acquire all necessary performance data. For the most part, NATOPS performance information is presented in a graphical format often requiring the user to transit several subcharts, which may be located on different pages, to obtain the desired performance parameter. This procedure is time consuming, prone to error, and impractical in-flight.

The purpose of this thesis is to propose a correction to these NATOPS deficiencies by transforming selected performance charts into interactive, user-friendly, computer software for a hand-held programmable calculator. This solution would enable aircrew to obtain performance data with increased accuracy, reduced time and effort, and permit in-flight use.

Previously there have been several successful efforts in NATOPS computerization. The most recent study [Ref. 2] developed software for the A-6 aircraft utilizing the Hewlett-Packard HP-41CV hand-held programmable calculator. This research demonstrated the feasibility of NATOPS computerization and was a prime motivator for this thesis.

C. GOALS

The first goal of this study was to generate a closed-form equation for each selected NATOPS chart or subchart. The equations were required to be of a form such that independent variables were the specific chart input parameters and the dependent variable, the output parameter. The equations used to "fit" each NATOPS chart had to allow an explicit calculation of the dependent variable. Furthermore, they had to consist of standard functions (no differentials/integral equations) which could be programmed on a calculator or computer.

Once the equations representing the performance charts had been derived, it was necessary to select the hardware which would be used for software design. The HP-41CV programmable calculator was selected due to its small size, relatively large memory capability (6.4 Kbytes), and successful use in the past.

Upon completion of the software development the ultimate goal of this research was the testing and implementation of the end product into the fleet.

II. APPROACH TO THE PROBLEM

The first and foremost problem encountered was the generation of the closed-form equation in a manner which accurately represented each performance chart with a minimum number of terms. For the majority of charts considered there were two independent input variables that yielded a single dependent output variable. This was visualized as a three dimensional surface in space.

To accomplish fitting an equation to a surface of irregular nature required the utilization of a numerical regression routine. These routines are numerous and have been developed into several software packages for main frame computers. The software chosen for this study was the Biomedical Computer Program (BMDP) statistical package [Ref. 3], installed on an IBM 3033 main frame computer located at the Naval Postgraduate School in Monterey, California. A regression is linear in nature no matter how many independent variables are involved. However, nonlinear functions may be used in a regression if they are first "linearized". For example, if the nonlinear functions x^2 , x^3 , and $\ln(x)$ are transformed into independent variables (transforms) U , Y , and Z , respectively, then a regression can be performed to yield an equation of the form:

$$S = aU + bY + cZ + d \quad (\text{eqn 2.1})$$

where a , b , and c , are the regression coefficients, d is the intercept, and S is the dependent variable. The specific BMDP routine used for the majority of charts analyzed was the "all possible subset" multiple regression routine (P9R) which allows the user to input a large selection of

and the NATOPS software program cards; several steps must be taken before the calculator can be used as described earlier.

1. Become familiar with the HP-41CV owner's manual and all peripherals operating instructions. While the basic user can avoid an in depth knowledge of the system, the initial set up requires someone who is familiar with the hardware and procedures listed in [Refs. 5,6,7].
2. With the extended memory and extended functions modules in their proper ports, and the card reader attached, loading the programs into main and extended memory can begin.
 - Load the following programs into extended memory: HIGW, VTOGW, HITQ, HOTQ, SE/EV, VNE, RNG, ENDA, and ENDB.
 - Load the following programs into main memory (in the order listed): MAIN, QD, DA, and IQAV.
3. Ensure the only programs in main memory are the ones listed above and erase any other programs.
4. Pack the programs in main memory.
5. Execute the program MAIN.

The calculator is now loaded and positioned to the main program. By pressing the user key the performance programs are assigned to their respective key locations and the calculator is ready for program execution.

are shown in the display. Some charts yield more than one performance parameter, so it is necessary to note each parameter displayed and then push the R/S key to continue execution.

6. Once all performance parameters have been calculated pushing R/S will display "NEXT" which tells the user he has been given all available output and the calculator is ready to execute the next program.
7. Before executing the PRE FLT program ensure the calculator is turned off. With the printer also turned off plug the printer input chord into the only remaining extension port. Turn the calculator and printer on, select the normal mode on the printer, and push the PRE FLT key. All other instructions remain the same.

B. GENERAL USER INFORMATION

The NATOPS software should generate accurate answers within the range of a selected performance chart. If data is entered erroneously, or in excess of a particular chart's range, the output will be in error.

In the cases where a chart has limitations such as density altitude [Ref. 4: p. 11-9], these have been taken into account within the program and the output will tell the user if they exceed that limitation. If the user is ever in doubt as to the validity of the calculator generated performance data, the NATOPS should be consulted.

C. INITIAL CALCULATOR PREPARATION

The basic use instructions assume the user has a calculator that has all the performance software installed. If the user merely has the calculator (with two extended memory modules, and an extended functions module), a card reader,

The programs listed in Table I are assigned to the corresponding keys shown in Figure A.1. The key marked "PRE FLT" performs all 10 programs and produces a hard copy of the output. This program requires that a printer is attached. To execute a program follow the steps presented below.

1. Turn the calculator on.
2. Ensure the calculator is in the user mode, if the word user is not visible in the display push the user key.
3. Find the key with the particular performance chart desired and push it. As the program is initiated the calculator will prompt the user for any needed information. The exact prompt meanings are defined below:
 - PA? FT - pressure altitude in ft.
 - OAT? C - outside air temperature in °C.
 - GW? LBS - gross weight in lbs.
 - WIND? KTS - head wind in kts.
 - CLIMB? FPM - climb rate in ft. per min.
 - FUEL? LBS - fuel on board in lbs.
4. Answer the prompt by pushing the corresponding numbered keys until the desired value is seen in the display. If a mistake is made, simply push the key with the horizontal arrow (far right column four keys from the top) and re-enter the number. If the number to be entered is negative (negative OAT), push the key marked CHS after the number has been entered in the display. When the desired number is displayed in the window push the key marked R/S (run/stop, bottom right key).
5. After all the prompts required have been answered the calculator will execute the program. While the calculator is working "PRGM" will be visible in the display. As the calculator generates answers they

NATOPS PERFORMANCE SOFTWARE USER'S GUIDE

A. BASIC USE

The NATOPS performance software designed for the HP-41CV calculator is simple and expeditious to use. The calculator keyboard configuration is depicted in Figure A.1. As you can see the first top two rows have abbreviated program names under the keys. The exact meaning of each performance chart abbreviation and its NATOPS [Ref. 4] page reference are contained in Table I below.

TABLE I
NATOPS Performance Chart Reference

DA	Density Altitude Chart	11-3
TQAV	Engine Performance Chart (Military Power 100% Nr)	11-5
HIGW	Max Gross Weight for Hovering in Ground Effect	11-9
VTOW	Max Gross Weight for Vertical Takeoff	11-11
HITQ	Torque Required to Hover in Ground Effect	11-12
HOTQ	Torque Required to Hover Out of Ground Effect	11-13
SE/EV	Ability to Maintain Flight One Engine Operating (100% Nr)	11-37
RNG	Max Range (100% Nr)	11-22/3
VNE	Indicated Never Exceed Speed	1-173
END	Max Level Flight Endurance	11-32/3

V. CONCLUSIONS AND RECOMMENDATIONS

From the results of this thesis it can be concluded that graphical NATOPS performance data can be computerized. To effectively accomplish this, computer oriented numerical regression routines must be utilized to generate closed-form equations.

Once the equations have been derived, computer software can be developed that executes the programs in an expeditious, accurate, and portable fashion. Furthermore, this software can be designed for virtually any type of computer from hand-held programmable calculators to personal computers.

It is recommended that the NATOPS performance software developed in this study be submitted to a fleet squadron or Fleet Replacement Squadron (FRS) for test and evaluation. Since the software can be utilized as is, with off the shelf Hewlett-Packard components, the cost of testing would be minimized. If this software proved to be fleet applicable, Hewlett-Packard should be contracted to develop plug-in application modules which would increase reliability and decrease execution time.

code. It should be noted that the regression equations can be programmed for use with any capable system. The results presented here are for the H-46D and modified H-46A (with T58-GE-10 engines) NATOPS performance charts referenced in Appendix A. Future modification of these charts would invalidate the performance software for those particular charts.

IV. RESULTS

At the onset of this study 10 different NATOPS performance charts were selected for computerization based on their significance and frequency of use. It was anticipated that the final performance chart programs would be too voluminous to be collectively stored within the HP-41CV memory. This would necessitate using an external mass storage device or executing individual programs piecemeal. Both of these alternatives would have had serious degrading effects, forcing the only other alternative of contracting Hewlett-Packard to hardwire one or more plug-in read-only-memory (ROM) modules containing the NATOPS software.

Fortunately, the majority of programs were reasonable in length. With efficient programming techniques employed, and two external memory modules in series with an extended functions module (total memory of 6.4 Kbytes), it became evident that all programs could be simultaneously stored within the calculator. With this in mind a master program was written which functioned as a software manager which assigned performance charts to key locations (Appendix A), called programs from inexecutable extended memory to the executable work space in main memory, and interactively communicated with the user. In general the master program functioned as a communications system and manager between the user and performance chart software in an interactive and user-friendly mode.

Appendix A contains the simple user instructions to execute any of the 10 listed NATOPS charts desired. With a printer attached a complete performance profile can be executed and printed for any mission plan. Appendix B lists all surface regression equations, flow charts, and program

Next a numerical regression was performed with the "method is none" option selected utilizing the standard fourth order polonomial (22 transforms) discussed earlier. The resulting output listed the terms excluded from the regression analysis due to exceeding tolerance limits (4), the regression R^2 (.99942), and other fit statistics. The high R^2 value indicated that the selected polonomial transforms were representative of the surface.

The next step was to determine if some of the retained transforms could be eliminated without significantly effecting the fit. The four out-of-tolerance terms were deleted from the transform selection and the program was executed with the "method is CP" option in effect. This resulted in an elimination of eight transforms while only degrading the R^2 value to .99936 (Appendix B: p. 36).

The equation for the surface was tested by writing a program stub and checked to ensure accuracy. Since the surface fit did not consider altitudes below the 2000 foot line, an interpolation routine was required in the final program to calculate torque when pressure altitude was between 2000 feet and sea level.

III. THE SOLUTION

The polonomial transform program yielded acceptable regression results in the majority of cases. For the performance charts that had difficult surfaces to fit, requiring as many as 38 transformed terms (Appendix B: p. 58), it was found to be advantageous to take the penalty of a large regression equation rather than fitting influence lines and interpolating between them. Of all the surfaces considered (23), only the single engine envelope (Appendix B: p. 64) required nonlinear transformed terms, specifically exponential and high order fractions.

A. EXAMPLE SURFACE REGRESSION ANALYSIS

The engine performance chart Figure 3.1 was chosen to illustrate the regression technique since it demonstrated the capability of numerical regression to generate an accurate closed form equation of a fairly irregular surface.

The first step in the solution of this performance chart was to create the data file for the regression program. Data sets were taken along each pressure altitude influence line at increments of 10° centigrade (C) with additional points added for the 4000 to 6000 foot altitude lines, due to their close proximity to each other. Each of the 155 data sets consisted of two independent variables (temperature and altitude) and the resulting dependent variable (torque). The sea level altitude line was omitted since it could be calculated directly (linear equation) and due to its discontinuities at -5 and 15 °C causing difficulties in fitting the surface.

transforms. If this algebra created numbers outside the tolerance range specified in the program (default tolerance = .0001), the "method is none" option would eliminate the offending variable, or transform, and continue execution. The resulting output contained the R^2 value along with other fit statistics and listed all terms eliminated for low tolerance. Performing a second iteration with the out-of-tolerance transforms eliminated, and with "method is CP" selected, allowed the BMDP software to analyze subsets of the remaining transforms. Performing this two step process yielded the best fit with fewest terms for each surface.

a performance chart were as accurate as possible and that the data file clearly defined the surface. Obviously, those surfaces that were irregular in nature required significantly more data sets than smoother or more "well behaved" surfaces. If a surface contained a sharp point or discontinuity, this portion of the surface was eliminated from the regression analysis due to the inability of the software to accurately fit aberrations.

The transformed variable selection was the key to successful regression analysis. Through experience one gained an intuitive feel for what type of transformed variables would yield a close fit to a surface. Fortunately, most of the surfaces responded well to regression analysis utilizing combinations of the independent variables raised to powers between one and four (polynomial regression). A standard polynomial regression program was developed containing all the possible polynomial terms up to the fourth order, for three and four dimensional surfaces.

For a few surfaces, obtaining a close fit by regression analysis incurred the penalty of retaining a large number of transformed terms. An alternative to this was to fit each of the depicted influence curves and develop the final computer software to interpolate between curves. The trade off with an interpolation scheme was increased accuracy at the expense of inordinate program size and complexity, causing the result to be unacceptable. In a few cases it became necessary to use nonlinear transforms of the independent variables such as exponentials, and high order fractional combinations of terms (Appendix B: pp. 64-65).

On the first execution of each regression analysis "method is none" was selected in the P9R program. This keyed the BMDP software to use all the offered transforms for the regression analysis. During execution, matrix algebra was performed with the independent variables and

transformed independent variables to be examined during the regression analysis. The P9R could be selected to either use all transformed variables offered (method is none), or perform the regression selecting subsets of the offered transforms and output the subset with the best fit statistics (method is CP).

The dominating criteria used to determine the best fit statistics was the squared multiple regression correlation (R^2). Accuracy was gauged by how close R^2 was to the ideal value of 1.0. The required R^2 for an acceptable fit was found to vary between performance charts, and was a function of what dependent output variable was being generated, the irregularity of the surface, and the number of independent input variables. For each chart multiple regression analyses were performed varying the offered transforms in number and/or type, until a closed form equation was generated that yielded output that was within the accuracy of manual chart interpolation.

The accuracy with which NATOPS chart could be read was subject to the individual chart's characteristics, but in general the following tolerances for dependent variables were established (for the regression analysis).

- airspeed: within 2 knots
- altitude: within 100 feet
- weight: within 150 pounds
- torque: within 1 %
- distance: within 1 mile
- time: within .1 hour

Prior to the execution of the regression program, a data file for each surface was created. The file consisted of data sets which were merely the independent variable values and the corresponding dependent variable value. For a three dimensional surface each data set consisted of three values. It was critical to ensure that the data sets extracted from

APPENDIX B

REGRESSION EQUATIONS AND SOFTWARE DOCUMENTATIONS

This appendix contains all of the regression equations generated for each NATOPS chart, associated flow charts, and resulting computer code. For the most part, the regression equations are listed in a tabular form due to their size. The actual equations are of the form shown in equation 2.1. The R^2 and standard error of estimate for each regression is also listed. The standard error of estimate is the average error expected over one standard deviation of the surface's area. The flow charts use standard symbology and depict the general programming logic but are not detailed in nature. The computer code listings are in the Reverse Polish Notation (RPN) language developed by Hewlett-Packard.

Table II lists all the variables used in the regression equations throughout the programs. Table III lists the programming flags used and their definitions. The following is a listing of memory storage registers and their contents.
